

and gray all over creating a single pattern in every individual bird. They're found in the marshes, pine forests, and woodlands across temperate north America with the ability to jump from branch to branch. They are small, square billed birds which have a diet regarding insects. As they jump along the branches on the trees, they stick their long and gilly beaks into the crevices within the trees in search of an insect. Like wood birds, they use their wings to migrate during the winter and fly, but they also use their wings to catch insects mid flight. These simple creatures live their life happily and without many issues besides humans and carnivorous birds like hawks. The Yellow Throated Warbler has a diversity stable population, but due to the threat of habitat loss, they are starting to be threatened. The higher demand of wood for houses and space for the increasing human population is removing their habitats. As the issue increases, the Yellow Throated Warblers expand their habitats north in search for more trees to live in. Along with this issue they have to occasionally stay alert for larger, more aggressive birds. They aren't made for fast flight and escaping, judging by the size of their beaks, so they are easy prey for fast and carnivorous birds. The yellow throated warbler doesn't have many particular qualities, however, their absence would negatively impact the ecosystem, supporting the fact that everything has a part to play in the world.
